Methods and Materials

Experimental. The experiments were carried out in a contamination-free ultrahigh vacuum chamber operated at base pressures of a few 10^{-11} Torr using magnetically suspended turbomolecular pumps (Osaka, TG1300MUCWB and TG420MCAB) backed by an oil-free scroll pump (Edwards, GVSP30).^{1,2} A polished silver substrate was interfaced to a closed-cycle helium cryostat (Sumitomo Heavy Industries, RDK415E) that can be moved vertically via an adjustable bellows (McAllister, BLT86) and rotated horizontally via a rotatable flange (Thermionics Vacuum Products, RNN-600/FA/MCO). After cooling the substrate to 4.6 ± 0.1 K, acetylene (C_2H_2 ; 99.9%, Airgas) and ammonia (NH_3 ; 99.999%, Matheson) were deposited onto the substrate surface through separate glass capillary arrays at partial pressures of 1.2×10^{-8} Torr for C_2H_2 and 0.8×10^{-8} Torr for NH_3 . A dry ice ethanol slush bath was used to remove the traces of acetone (CH_3COCH_3) in the acetylene.³ The formulae of interested ion signals were verified using isotopically substituted ice mixtures including $^{13}\text{C}_2\text{H}_2-\text{NH}_3$ ($^{13}\text{C}_2\text{H}_2$; >99 $^{13}\text{C}\%$, Cambridge Isotope), $\text{C}_2\text{H}_2-^{15}\text{NH}_3$ ($^{15}\text{NH}_3$; >98 $^{15}\text{N}\%$, Sigma Aldrich), and $^{13}\text{C}_2\text{H}_2-^{15}\text{NH}_3$. To measure the ice thickness, a photodiode recorded interference fringes between helium-neon laser (632.8 nm) reflections of the ice surface and silver substrate during the ice deposition.⁴ The ice thickness and the acetylene-to-ammonia ratio were determined to be $1,000 \pm 100$ nm and 1.0: (1.0 ± 0.2), respectively.⁵ After deposition, each ice was then processed with energetic electrons (5 keV; SPECS EQ 22/35) at a 70° angle of incidence at a current of 100 nA for 60 minutes, which correspond to doses of 5.0 ± 0.8 eV per C_2H_2 molecule and 3.5 ± 0.6 eV per NH_3 molecule,⁵ simulating the irradiation of interstellar ices by secondary electrons generated in the track of GCRs in cold molecular clouds aged around 2×10^7 years.⁶ The average penetration depth (350 ± 30 nm) of the energetic electrons is significantly less than the ice thickness ($1,000 \pm 100$ nm), preventing energetic electron-initiated interactions between the substrate and ice mixtures. A Fourier transform infrared (FTIR) spectrometer (Thermo Electron, Nicolet 6700) monitored the infrared spectra of ice mixtures before, during, and after irradiation with a spectral resolution of 4 cm^{-1} .

After irradiation, the ice was heated from 5 K to 300 K at a rate of 1 K minute⁻¹ (temperature-programmed desorption, TPD) to release molecules into the gas phase. A cryogenic silicon diode sensor (Lakeshore DT-670) was used to measure the temperature of the silver substrate, which was precisely regulated between 5 K and 300 K, with a precision of ± 0.1 K, by a programmable

temperature controller (Lakeshore 336). During the TPD, subliming molecules were ionized by vacuum ultraviolet (VUV) single-photon ionization (SPI); individual isomers were selectively ionized by two-photon resonance-enhanced multiphoton ionization (REMPI). Tunable VUV photons were generated through the non-resonant (10.49 eV) or resonant (7.90 eV, and 8.10 – 8.27 eV) four-wave mixing method with the detailed parameters listed in Table S2. The synchronized laser beams were generated from two dye lasers (Sirah Lasertechnik GmbH, Cobra-Stretch) pumped by two pulsed (30 Hz) Nd: YAG lasers (Spectra-Physics, Quanta Ray Pro 250 and 270). Xenon (Specialty Gases, 99.999%) or krypton (Specialty Gases, 99.999%) gas was used as a nonlinear medium. The ultraviolet (UV) photons were generated via the frequency doubling process in a dye laser pumped by the third harmonic (355 nm) of a Nd:YAG laser. To determine the [1 + 1] REMPI wavelengths of aniline (**4**) and indole (**2**), separate experiments were performed with processed C₂H₂–NH₃ ice under the same experimental conditions. During the TPD, the laser wavelengths were scanned over the relevant wavelength ranges; the wavelengths were calibrated with a wavelength meter (Coherent, Wavemaster). Wavelengths at 283.817 nm (4.369 eV) and 293.842 nm (4.219 eV) were found to produce the strongest signals for aniline (Figure S3) and indole (**2**) (Figure S4), respectively, and therefore they were used to detect aniline (**4**) and indole (**2**) molecules in separate irradiation experiments. The ionization laser beam was separated spatially by a biconvex lithium fluoride lens (Korth Kristalle, R₁ = R₂ = 131.2 mm) in an off-axis geometry and passed 2.0 ± 0.5 mm over the ice surface to ionize the subliming molecules. The resulting ions were then detected by a reflectron time-of-flight mass spectrometer (ReToF-MS; Jordan-TOF products) equipped with two microchannel plates in chevron geometry. The ion signals were amplified by a preamplifier (Ortec 9305), shaped in a discriminator (Advanced Research Instruments Corp., F100-TD), and finally recorded by a multichannel scaler (FAST ComTec, MCS6A). The ionization laser was synchronized with the multichannel scaler through a digital delay pulse generator (Quantum Composers, 9518). During TPD, each recorded spectrum was integrated over 3600 sweeps (2 minutes) in bins of 3.2 ns width. The resolving power (m/Δm) of this instrument was measured to be around 360 in the considered range. It is worth noting that a blank experiment was performed with C₂H₂–NH₃ ice under identical conditions but without electron irradiation; no ion signals at the mass-to-charge ratios (*m/z*) of 67, 93, and 117 were observed (Figure S7). An additional experiment with C₂H₂–hydrogen cyanide (HCN, 5% seeded

in helium) ice irradiated with a lower dose (20 nA, 15 minutes) was recorded at a photon energy of 10.49 eV (Figure S12).

Computational. Geometry optimization of various reactants, products, intermediates, and transition states involved in the variety of considered radical-molecule and radical-radical reactions leading to the formation of pyrrole, indole, and aniline were carried out using density functional theory with the ω B97X-D functional by Chai and Head-Gordon⁷ and 6-311G(d,p) basis set. Vibrational frequencies for each stationary structure were evaluated at the same ω B97X-D/6-311G(d,p) level of theory to verify whether the structure is a local minimum or a first-order saddle point (transition state) and to obtain the zero-point vibrational energy (ZPE) correction. Following the optimization, single-point energies were further improved using either explicitly correlated coupled cluster calculations with single and double excitations and perturbative treatment of triple excitations, CCSD(T)-F12,^{8,9} with Dunning's cc-pVTZ-F12 basis set¹⁰ (for the pyrrole and aniline formation reactions), or employing the G3(MP2,CC) model chemistry scheme¹¹⁻¹³ (for indole formation). Relative energies computed at the CCSD(T)-F12/cc-pVTZ-F12// ω B97X-D/6-311G(d,p) + ZPE(ω B97X-D/6-311G(d,p)) and G3(MP2,CC)// ω B97X-D/6-311G(d,p) + ZPE(ω B97X-D/6-311G(d,p)) levels of theory are anticipated to be accurate within 4 and 8 kJ mol⁻¹, respectively^{13,14}. All electronic structure calculations were performed using the Gaussian 09 and Molpro 2015 program packages^{15,16}. Besides the potential energy surfaces presented in Figures 5–6, our electronic structure calculations reveal other reaction pathways leading to the formation of pyrrole (**3**) (Figures S13–S19) and indole (**2**) (Figures S20–S25). The computed Cartesian coordinates and vibrational frequencies of optimized structures (reactants, products, intermediates, and transition states) are listed in Table S3, which includes 88 reaction intermediates and 93 transition states. It is worth noting that gas-phase calculations may overestimate the reaction barrier because nearby molecules could participate in the reactions in the ice phase,¹⁷⁻¹⁹ in particular, to be directly involved in the H transfer processes (Figures S13, S14, S16, S18, and S19).
